  - 6.1. Red básica
    - 6.1.1. Relación de coordenadas
    - 6.1.2. Reseñas de los vértices
  - 6.2. Puntos de apoyo
    - 6.2.1. Relación de coordenadas
  - 6.3. Cálculos y observaciones
    - 6.3.1. Proyección cónica conformante Lambert
    - 6.3.2. Cálculo de las líneas base

### 3. CARTOGRAFÍA Y TOPOGRAFÍA

#### 1. CARTOGRAFÍA

La cartografía básica para la realización del proyecto ha sido confeccionada a partir de dos vuelos realizados a escalas 1:25.000 y 1:5.000.

El vuelo a escala 1:25.000 contiene la totalidad del proyecto, y fue realizado en Mayo de 2000 por la empresa AEROFOTO (Centroamericana, S.A.), la cartografía obtenida es expedida, siendo ésta a escala 1:5.000, con equidistancia entre curvas de nivel de cinco metros.

El vuelo a escala 1:5.000 comprende la zona de estudio desde San José hasta el río Virilla y fue realizado en Mayo de 2000 por la empresa AEROFOTO (Centroamericana, S.A.), la cartografía obtenida a partir de dicho vuelo ha sido confeccionada a partir del correspondiente apoyo de campo.

La cartografía ha sido obtenida por los métodos fotogramétricos, digitalizada con una precisión correspondiente a escala 1:1.000, con equidistancia de 1 m entre curvas de nivel.

El apoyo de campo fue realizado por la empresa GETINSA-NOVOTECNI Y ASOCIADOS, S.A., y la restitución por la empresa FOTOPLÁN.

La restitución ha sido analítica, disponiéndose de la misma en soporte magnético.

#### 2. TOPOGRAFÍA

Los trabajos topográficos han consistido en el apoyo fotogramétrico de campo de un vuelo a escala 1:5.000 para el posterior levantamiento de la cartografía base a escala 1:1.000 con equidistancia entre curvas de nivel de un (1) metro.

También se han tomado numerosos puntos de la carretera Braulio Carrillo a su paso por el Parque Nacional para facilitar el perfecto encaje de la cartografía.

#### 3. ENLACE A LA RED GEODÉSICA

##### 3.1. Proyección y referencias cartográficas

El sistema de coordenadas para Costa Rica se basa en la Proyección Cónica Conforme Lambert, referida al elipsoide Clarke 1866, esta proyección fue facilitada por el I.G.N. de Costa Rica así como las coordenadas y croquis de los Vértices Geodésicos cercanos a la zona de estudio.

De un total de seis Vértices Geodésicos facilitados por el I.G.N. solo se encontraron dos, SASA y CURRI, el resto ha desaparecido.

Lo mismo ocurre en altimetría que de todos los puntos de nivelación (B.M.) facilitados por I.G.N. los encontrados, pueden pertenecer a distintas líneas de nivelación ya que una vez comprobados presentan errores importantes entre ellos.

Con lo que al no poder disponer de un sistema de referencia formado por lo menos con cuatro vértices geodésicos y cuatro puntos de nivelación en la zona de estudio ya que estos han desaparecido o presentan errores, se ha utilizado como sistema de referencias las coor-

nañas obtenidas en el sistema WGS-84 y como proyección la facilitada por el I.G.N. de Costa Rica (proyección Lambert) y referida al elipsoide Clarke 1866.

### **3.2. Metodología y cálculo**

El trabajo se ha realizado mediante técnicas GPS, contando para su ejecución con un equipo WILD System 300, compuesto por receptores de doble frecuencia WILD SR-399 que trabajan con observables de código P y unidades de control portátiles WILD CR-333.

El método de observación utilizado ha sido el diferencial mediante observaciones en estático desde estaciones de referencia temporales, obteniendo los incrementos de coordenadas en el sistema egocéntrico WGS-84 desde el equipo de referencia al punto observado.

Los tiempos de observación han sido determinados por el número y geometría (GDOP) de los satélites operativos, las perturbaciones de la ionosfera y por la longitud de las líneas base.

Sobre el terreno se ha creado un fichero de datos para cada vértice geodésico, observado con su numeración definitiva.

El proceso de datos para el cálculo de las líneas base y resolución de ambigüedades, se ha realizado mediante el software SKI de la casa WILD-LEICA, obteniendo a partir de las observaciones GPS, las coordenadas de todos los puntos en el sistema WGS-84.

Se adjuntan los listados del cálculo de cada línea base, donde se incluye toda la información recabada en el proceso, los resultados obtenidos y el error medio cuadrático (r.m.s.) de cada observación.

Para este proyecto se han utilizado los datos obtenidos de los vértices que sirvieron de apoyo para la obtención de la cartografía utilizada en el estudio de factibilidad para la conexión de obra de tres viaductos urbanos en la ciudad de San José, además de estos vértices se han añadido un total de cinco nuevos vértices desde los cuales poder dar puntos de la carretera Braulio Carrillo y así facilitar su encaje en la cartografía.

Los vértices han quedado situados en las inmediaciones de la zona del proyecto y a una distancia media de aproximadamente 5000 m.

El sistema de señalización ha sido el más adecuado para cada tipo de terreno, empleando clavos de acero, de forma que quede garantizada su permanencia.

El total de vértices implantados ha sido de 9 unidades.

De cada vértice se entrega una ficha con su numeración y coordenadas, tipo de señal, croquis, leyenda de situación y fotografía.

### **4. APOYOS DE CAMPO**

Se ha observado la malla de puntos de apoyo necesarios para la posterior restitución analítica.

Los puntos de apoyo han sido observados con la misma metodología GPS que los vértices, aplicando los mismos parámetros de transformación para el cálculo de sus coordenadas.

Los puntos de apoyo quedan identificado en los fotogramas por medio de un pinchazo realizado sobre terreno, un círculo de aproximadamente un centímetro de diámetro y la rotulación de la numeración definitiva.

Los listados de coordenadas de los puntos de apoyo se adjuntan en el apartado 6.2.1.

## 5. PRECISIONES

### 5.1. Precisiones

Dadas las características técnicas de los instrumentos GPS utilizados (equipos de doble frecuencia) y la metodología de observación (método estático), las precisiones que se obtienen en la observación de un punto tienen como errores máximos:

Planimetría - XY -: 5 a 10 mm + 1 ppm

Altimetría - Z -: 5 a 10 mm + 2 ppm

Siendo ppm, partes por millón de la longitud de la línea base. Es decir, para una longitud entre el receptor de la estación de referencia y un punto observado a 5.000 metros, el error máximo cometido es:

Planimetría - XY -: 10 mm + 5 mm = 15 mm

Altimetría - Z -: 10 mm + 10 mm = 20 mm

En los listados de puntos se puede observar los residuos obtenidos en las observaciones de campo y el error medio cuadrático (r.m.s.) de cada observación.

### 5.2. Desarrollo de los cálculos GPS

A continuación se detallan los pasos seguidos en el cálculo de coordenadas a partir de observaciones GPS con el programa SKI de la casa WILD-LEICA.

#### 5.2.1. Desarrollo del proceso

Como primer paso el programa carga las observaciones GPS obtenidas en campo mediante receptores de doble frecuencia y por el método diferencial y observables C/A, P y FA-SE.

Después de realizar, en su caso, las correcciones de alturas de instrumento o denominación de los puntos, el programa calcula los vectores (líneas base) entre el equipo referencia y los móviles (Rover) observados en el mismo intervalo de tiempo.

Con estas líneas base se obtienen las coordenadas en el sistema WGS-84 de los puntos observados, procediendo a su ajuste por mínimos cuadrados de los triángulos y polígonos formados con observaciones redundantes.

Una vez obtenidas las coordenadas WGS-84 definitivas de todos los puntos, estas coordenadas son referidas al sistema local para lo cual se utiliza como proyección la facilitada por el I.G.N. de Costa Rica (proyección Lambert) y referida al elipsoide Clarke 1866.

## 5.2.2. Listados del programa SKI

### 5.2.2.1. Líneas Base

Coordenadas finales: coordenadas en WGS-84 calculadas en cartesianas y geográficas del punto móvil con respecto a la referencia, la distancia entre ambos y el error medio cuadrático.

#### *Project Setting*

Especifica la denominación y versión del programa, nombre del proyecto, sistema de coordenadas y hora local utilizada.

#### *Processing Parameters*

Parámetros utilizados en las observaciones de campo y su cálculo.

#### *Baseline overview*

Relación de las líneas base calculadas, definiendo la referencia, día y hora de la observación, cálculo de las ambigüedades y método de observación, estático, cinemático o en tiempo real.

#### *New static chain*

Relaciona para cada línea base los parámetros y cálculos utilizados: información general durante la observación, tipo de receptores y antenas, número de medidas, ambigüedades y satélites en ambas frecuencias.

### 6.3. Cálculos y observaciones

### 6.3.1. Proyección cónica conformante Lambert

#### 7. CÁLCULO DE LOS ACÍMETOS

Después que se haya obtenido el valor de  $\phi$  en el punto A, hay que determinar los acímetros de cada uno de los puntos B y C, para lo cual se debe utilizar la Proposición 1, que establece que la suma de los ángulos de un triángulo es igual a  $180^\circ$ . En la Figura 3 se muestra un triángulo con los ángulos  $\phi$  en el punto A,  $\alpha$  en el punto B, y  $\beta$  en el punto C. Se debe tener en cuenta que la suma de los ángulos  $\phi$ ,  $\alpha$  y  $\beta$  es igual a  $180^\circ$ .

En el triángulo ABC, se tiene que  $\phi + \alpha + \beta = 180^\circ$ . Si se conoce el valor de  $\phi$  en el punto A, se puede calcular el valor de  $\alpha$  en el punto B y el valor de  $\beta$  en el punto C. Esto se hace utilizando la Proposición 1, que establece que la suma de los ángulos de un triángulo es igual a  $180^\circ$ .

en donde S y T son interpolados para  $\theta$  y  $\frac{\theta}{2}$  respectivamente. Se aconseja el uso de este procedimiento en lugar de obtener  $\sin \theta$  y  $\tan \frac{\theta}{2}$  directamente de las tablas

FIGURA 4

trigonométricas logarítmicas a causa de la variación rápida no lineal en las funciones trigonométricas logarítmicas para ángulos angostos. Los logaritmos hasta 8 cifras se necesitan para conseguir una precisión de ,01 metro en X y Y. En la Figura 4 hay una forma sugerida con un ejemplo de cálculo.

d. Coordenadas geográficas de coordenadas de cuadrícula,—por logaritmos Las fórmulas para el cálculo de  $\phi$  y  $\lambda$  de X y Y por medio de logaritmos

son semejantes a aquéllas usadas en el método mecánico. Ellas son:

$$X' = X - FE$$

$$\log \tan \theta = \log X' - \log Y'''$$

$$\log \Delta\lambda = \log \theta + \text{colog sen } \phi_0$$

$$\log Y'' = \log X' + \log \tan \frac{\theta}{2}$$

$$Y' = Y - Y''$$

La función T debe emplearse para obtener  $\log \theta$  de  $\log \tan \theta$  y también para conseguir  $\log \tan \frac{\theta}{2}$  de  $\log \frac{\theta}{2}$  (véase el párrafo 6c susodicho).  $\phi$  se obtiene de Y' por interpolación inversa en Tabla I. Se necesita logaritmos hasta 8 cifras para conseguir una precisión de ,001" en  $\phi$  y  $\lambda$ .

En la Figura 5 hay una forma sugerida con un ejemplo de cálculo.

FIGURA 5

## 7. CALCULO DE LOS ACIMUTES

Siempre que se usan visuales de más de una milla, hay que distinguir entre dos clases de acimutes de cuadrícula: el acimut geodésico proyectado y el acimut plano. Si trazamos una línea de mira o lo que resulta casi igual, una línea geodésica, en una Proyección Lambert, resulta que la curvatura es cóncava hacia el paralelo de origen como se ve en la Figura 6. Es la más grande para las líneas de este al oeste y la más pequeña para las líneas de norte al sud; también es pequeña cerca del paralelo de origen y más grande en los paralelos exteriores de la zona.

Si un observador coloca su teodolito en punta A y mira a B, su línea de mira así proyectada no apuntará a lo largo de la línea recta AB sino a lo largo de la línea curva de manera que él pudiera ver el árbol en línea con el punto B. Si AC se traza tangente a la línea curva AB al punto A, resulta que el ángulo al punto A en sentido

horario del norte de cuadrícula a AC es el ángulo que el eje óptico del telescopio del teodolito formará con el norte de cuadrícula cuando esta apuntado a B; y este ángulo se llama el acimut geodésico proyectado y se indica por T. Es una cantidad

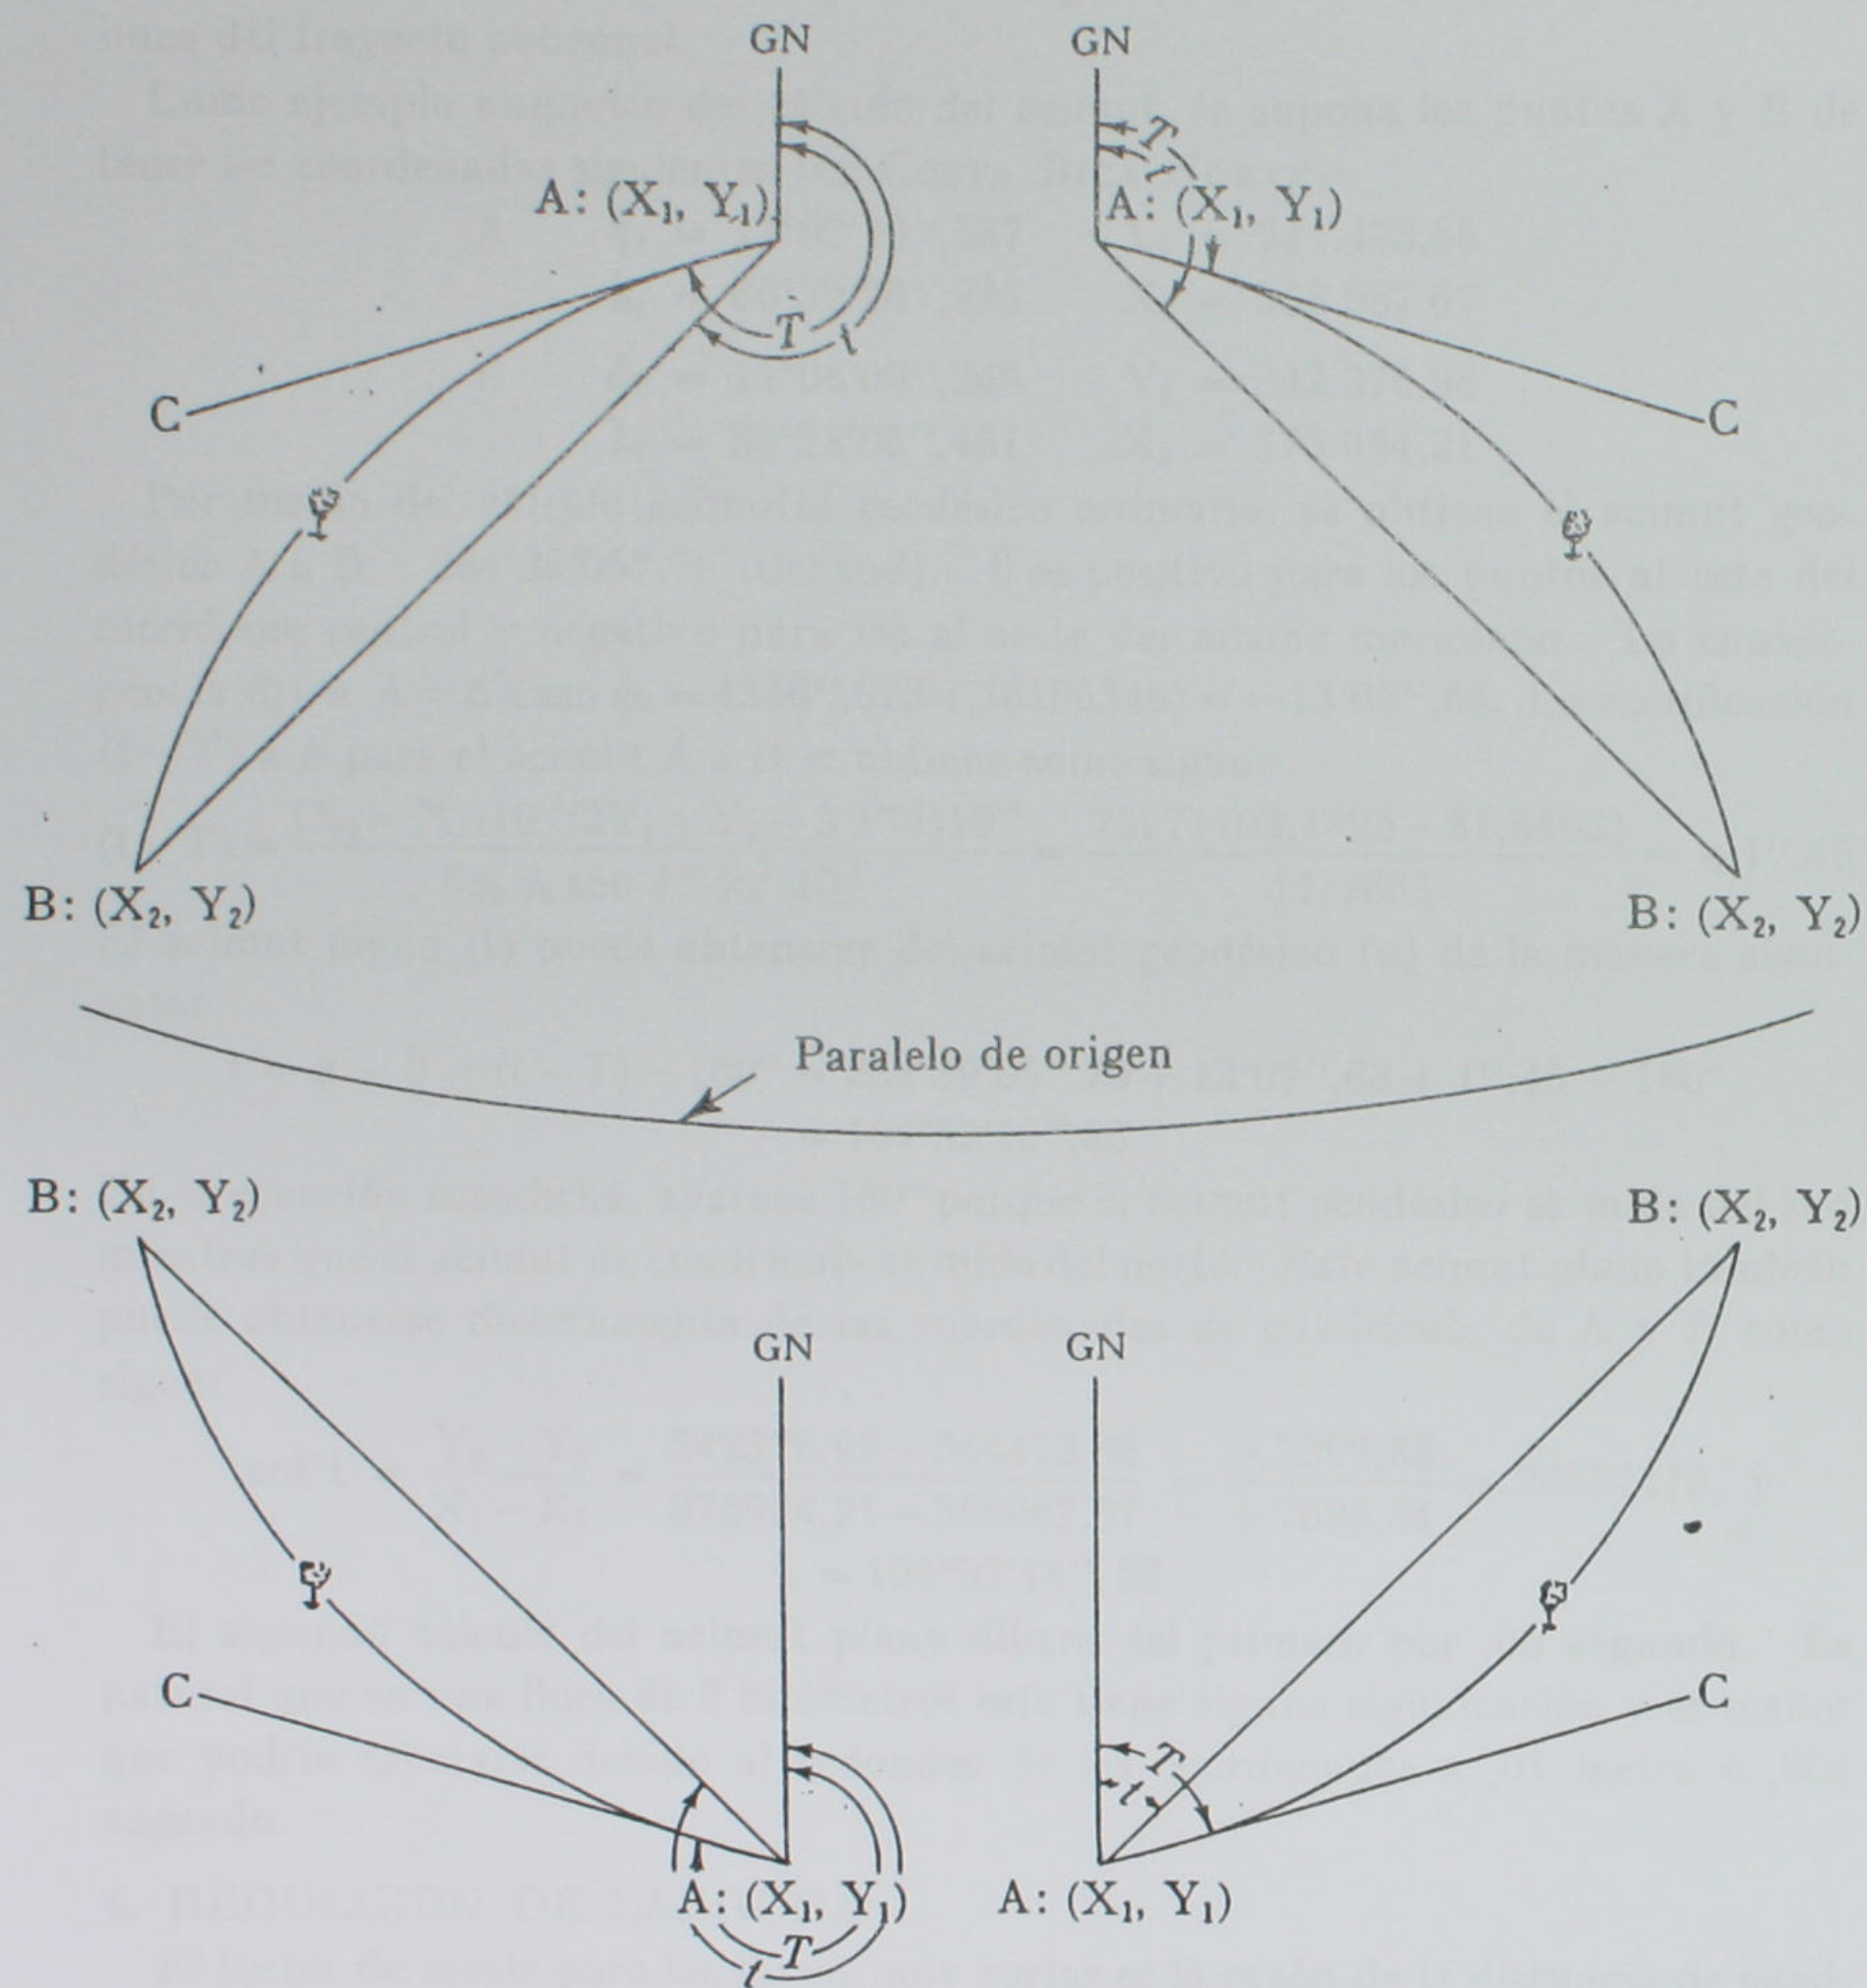

FIGURA 6

verdadera físicamente que puede obtenerse del acimut geodésico sencillamente por medio de la aplicación de la convergencia ( $\theta$ ). La diferencia entre dos acimutes geodésicos proyectados de líneas de vista de intersección equivale al ángulo

horizontal a la intersección formada por estas líneas cuando este medido por un observador.

El ángulo en sentido horario del norte de cuadrícula a la línea recta AB (recta solamente en la proyección; actualmente curva) se llama el acimut plano de la línea A a B. Si las coordenadas de cuadrícula de A y B son establecidas, entonces es fácil determinar t de cualquiera de las formas siguientes:

$$\tan t = \frac{X_2 - X_1}{Y_2 - Y_1} \quad \cot t = \frac{Y_2 - Y_1}{X_2 - X_1}$$

cuando el subscrito 1 se refiere al punto A y el subscrito 2 a B. La fórmula que hace la función menor que la unidad es la que debe emplearse. El acimut plano (t),—nada parecido al acimut geodésico proyectado (T),—es una función matemática cuya utilidad consta del hecho de que es fácil calcularse de las coordenadas de cuadrícula y es el acimut que tiene que emplearse cuando hacen cálculos en coordenadas de cuadrícula. El nombre acimut de cuadrícula se emplea tanto para el acimut geodésico proyectado como para el acimut plano cuando puede ignorarse la diferencia. La diferencia se llama la rectificación (t-T).

$$t - T = \frac{(X_2 - X_1)}{6\rho_0 \nu_0 \text{ sen } 1'' k_0^2} (2Y_1 + Y_2 - 3FN)$$

| CONSTANTES                                     | COSTA RICA NORTE | COSTA RICA SUD |
|--|------------------|----------------|
| $6\rho_0 \nu_0 \text{ sen } 1'' k_0^2 10^{-8}$ | 11,7579          | 11,7566        |
| $3FN10^{-4}$                                   | 81,5463          | 98,3961        |

En los cálculos tocante a la cuadrícula es importante que se usa el acimut plano más bien que el acimut geodésico proyectado siempre que la diferencia entre los dos no sea insignificante. Esta diferencia, la rectificación (t-T), siempre es pequeña. En los cálculos de triangulación, la aplicación de la rectificación (t-T) es de la misma importancia que la aplicación del exceso esférico en los cálculos geodésicos. Hay que tener presente que la diferencia entre dos posiciones observadas no es el ángulo plano. La rectificación (t-T) tiene que aplicarse primero a cada dirección y entonces las diferencias de estas direcciones resultarán en ángulos planos. La rectificación (t-T) puede ignorarse enteramente en el trayecto poligonal salvo en el caso de un punto de mira muy distante. Es preciso generalmente considerar la rectificación (t-T) solamente al empezar y terminar los acimutes del trayecto poligonal y en este caso únicamente cuando la marca del acimut queda a varias millas de distancia. Si el acimut de arranque se manifiesta como un acimut plano (t) y se ha establecido de las coordenadas de cuadrícula por medio de la fórmula de tangentes, el ángulo observado debe convertirse en ángulo plano por medio de la aplicación de la rectificación (t-T) antes de agregar o substraerlo del acimut de arranque. No obstante, si el acimut de arranque se expresa como un acimut geodésico o astronómico ( $\alpha$ ), puede convertirse en acimut geodésico proyectado (T) por medio de la aplicación de la fórmula  $T = \alpha - \theta$ . La rectificación (t-T) podría aplicarse a este acimut geodésico proyectado para obtener el aci-

mut plano pero en vista de que la misma rectificación (t-T) debe aplicarse también al ángulo observado para obtener un ángulo plano, el efecto de esta rectificación quedaría nulo. Por eso, el ángulo observado puede aplicarse directamente al acimut geodésico proyectado para conseguir el acimut plano de la primera línea del trayecto poligonal.

Como ejemplo numérico del cálculo del acimut, se supone los puntos A y B de tener las coordenadas siguientes (en COSTA RICA NORTE):

$$\begin{array}{l} \text{A} \quad \phi_1 = 11^\circ 07' 16'', 537 \quad Y_1 = 344.473,86 \\ \quad \quad \lambda_1 = 85^\circ 32' 26'', 923 \quad X_1 = 368.087,67 \\ \text{B} \quad \phi_2 = 11^\circ 06' 09'', 246 \quad Y_2 = 342.376,98 \\ \quad \quad \lambda_2 = 85^\circ 28' 06'', 461 \quad X_2 = 375.984,21 \end{array}$$

Por medio del cálculo acimutal geodésico ordinario, se obtiene el acimut geodésico A a B,  $284^\circ 39' 05'', 70$  (del sud).  $\theta$  es positivo para los puntos al este del meridiano central y negativo para los al oeste del mismo meridiano. La convergencia ( $\theta$ ) a A =  $\Delta\lambda \text{ sen } \phi_0 = 4346'', 923$  ( $,18166346$ ) =  $-13' 09'', 68$ . La rectificación (t-T) a A para el acimut A a B se obtiene como sigue:

$$(t-T) = \frac{(X_2 - X_1) 10^{-4} (2Y_1 + Y_2 - 3 \text{ FN}) 10^{-4}}{6 \rho_0 \nu_0 \text{ sen } 1'' k_0^2 10^{-8}} = \frac{,7897 (103,1325 - 81,5463)}{11,7635} = +1'', 45$$

El acimut plano (t) puede obtenerse del acimut geodésico ( $\alpha$ ) de la manera siguiente:

$$t = \alpha - \theta + (t-T) - 180^\circ = 284^\circ 39' 05'', 70 + 13' 09'', 68 + 1'', 45 - 180^\circ = 104^\circ 52' 16'', 83$$

En la ecuación susodicha, aparece  $180^\circ$  porque el acimut geodésico se mide del sud mientras que el acimut de cuadrícula se mide del norte. Este acimut plano también puede obtenerse directamente de las coordenadas de cuadrícula de A y B como sigue:

$$\cot t = \frac{Y_2 - Y_1}{X_2 - X_1} = \frac{342376,98 - 344473,86}{375984,21 - 368087,67} = \frac{-2096,88}{+7896,54} = ,26554415, \text{ y} \\ t = 104^\circ 52' 16'', 88$$

El segundo cálculo del acimut plano difiere del primero por ,05 segundo. Es natural que en una línea de 8 kilómetros esto tiene alguna significación y es menor que podría esperarse debido al redondeo de las coordenadas a ,01 metro ó ,001 segundo.

## 8. REDUCCION DE LARGURA

El factor de escala para las líneas muy cortas es la razón de la distancia de cuadrícula a la distancia verdadera. Su valor puede obtenerse por interpolación en la Tabla I. El factor de escala interpolado para obtener la latitud media de los puntos terminales de una línea puede emplearse como factor de reducción de largura para las líneas hasta 28 kilómetros de largo, con el resultado de que el error proporcional no excederá un millonésimo. Cuando se conocen las coordenadas de cuadrícula sin conocer las coordenadas geográficas de los puntos terminales de una

línea, es más conveniente hacer uso de la fórmula basada en las coordenadas de cuadrícula. El uso de la siguiente fórmula para líneas que no sobrepasan 50 kilómetros limitará el error proporcional a un millonésimo:

$$\bar{k} = k_0 + c_1 Y_m^2 + c_2 Y_m X_m^2 + c_3 \Delta Y^2$$

en donde

$\bar{k}$  = la largura de cuadrícula de una línea dividida por la largura geodésica de la línea.  $X_1, Y_1$  y  $X_2, Y_2$  son las coordenadas de cuadrícula de los puntos terminales de la línea.

$$\begin{array}{l} X_m = \frac{X_1 + X_2}{2} - \text{FE} \quad Y_m = \frac{Y_1 + Y_2}{2} - \text{FN} \\ \Delta X = X_2 - X_1 \quad \Delta Y = Y_2 - Y_1 \\ c_1 = \frac{1}{2k_0 \rho_0 \nu_0} \quad c_2 = -\frac{t_0(2 - \eta_0^2)}{4k_0^2(\rho_0 \nu_0)^{3/2}} \\ c_3 = \frac{1}{24k_0 \rho_0 \nu_0} \end{array}$$

|                      | COSTA RICA NORTE | COSTA RICA SUD |
|----------------------|------------------|----------------|
| $c_1 \times 10^{12}$ | + ,01236 94      | + ,01237 08    |
| $c_2 \times 10^{18}$ | - ,00035 82      | - ,00030 72    |
| $c_3 \times 10^{12}$ | + ,00103 08      | + ,00103 09    |

Se nota que esta es la fórmula clásica para el factor de escala en términos de las coordenadas de cuadrícula, salvo en el caso de la expresión matemática  $c_3$ . Por eso, esta expresión indica la suma que debe agregarse al factor de escala del punto medio de la línea para producir la razón de la largura de cuadrícula a la largura geodésica de la línea.

El ejemplo que sigue indica el método de determinar las longitudes geodésicas cuando se sabe las coordenadas de cuadrícula de los puntos terminales de una línea.

| COSTA RICA NORTE |                    |                    |
|------------------|--------------------|--------------------|
| Punto dado A     | $X_1 = 368.087,67$ | $Y_1 = 344.473,86$ |
| Punto C          | $X_2 = 382.308,74$ | $Y_2 = 296.351,24$ |
|                  | FE = 500.000,00    | FN = 271.820,52    |

$$X_m(10^{-6}) = \frac{1}{2} (,382309 + ,368088) - ,500000 = -,124802$$

$$Y_m(10^{-6}) = \frac{1}{2} (,296351 + ,344474) - ,271821 = +,048592$$

$$\Delta Y(10^{-6}) = ,296351 - ,344474 = -,048123$$

$$\bar{k} = k_0 + c_1 10^{12} (Y_m 10^{-6})^2 + c_2 10^{18} (Y_m 10^{-6}) (X_m 10^{-6})^2 + c_3 10^{12} (\Delta Y 10^{-6})^2$$

$$= ,9999570 + ,0000292 - ,0000003 + ,0000024$$

$$\bar{k} = 0,9999883$$

$$\text{Largura de cuadrícula de la línea} = \sqrt{(\Delta X)^2 + (\Delta Y)^2} = \sqrt{(14221,07)^2 + (48122,62)^2}$$

$$= 50179,93 \text{ metros}$$

$$\text{Largura geodésica} = \frac{\text{Largura de cuadrícula}}{k} = \frac{50179,93}{0,9999883} = 50180,52$$

Largura geodésica del cálculo geodésico = 50180,51 metros

En este ejemplo el factor de reducción da un resultado en que el error es cero.

El error máximo de una parte en un millón ocurre ramamente.

| $\phi$ | R              | Y'          | $\Delta 1''$ | k          |

Detailed description:

El punto está localizado aproximadamente 13 Kmts. al Sur de Carrillo; 15 Kmts al N.W. de Llano Grande de Cartago; 15.5 Kmts. al Norte de Tres Ríos y 18 Kmts. al N.E. de San José. Está en potreros de la finca, propiedad del Sr. Sergio Zamora, situada en la falda Sur de los cerros conocidos con el nombre de Surki y Las Tres Marías.

Para llegar, partiendo de la esquina Norte de la Iglesia de Santo Domingo de Heredia, con rumbo N.E., por la carretera que conduce a San Luis Gonzaga de Santo Domingo de Heredia; a 1.2 Kmts. se encuentra una bifurcación de la carretera, se sigue a la derecha (Este) y a 2.5 Kmts. (de la bifurcación) y 3.7 Kmts. de Santo Domingo, se llega a San Luis. De aquí tome el camino que va con rumbo Norte 2 Kmts. hasta llegar a la lechería "La Yerba Buena"; se continua siempre por el mis-

mo camino con rumbo N.E. 3.5 Kmts. llegando a una casa que está en el costado Oeste de la vía; se sigue unos 500 mts. al Norte, en donde hay unos cipreces que sirven de cerca; el camino dobla al Oeste 100 mts. y luego toma de nuevo al Norte; 300 mts. al Norte de los cipreces se encuentra la loma en que está la estación.

La estación es un disco de bronce de 9 centímetros de diámetro, colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale 0.05 mts. del suelo, estampado: SURKI, 1956.

El punto de referencia # 1 es un disco de bronce de 6 centímetros de diámetro, colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale 0.05 mts. del suelo y está 0.335 mts. más alto que la estación, estampado: SURKI, R.M. 1, 1956.

El punto de referencia # 2 es un disco de bronce de 6 centímetros de diámetro colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale 0.08 mts. del suelo y está 3.080 mts. más alto que la estación, estampado: SURKI, R.M. 2, 1956.

El Acimut está localizado aproximadamente a 540 mts. del vértice con rumbo S 30 E, en una pequeña loma cubierta de zacate y a 2 mts. al Norte de un árbol de Copal, en propiedad del Sr. Damiam Bolaños. Es un disco de bronce de 9 centímetros de diámetro, colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale 0.07 mts. del suelo, estampado: SURKI, ACIMUT, 1956.  
*elevation trigonométrica de Acimut 1543.57 m (1974)*

\* Refers to notes in manuals of triangulation and state publications of triangulation. † Direction-angle measured clockwise, referred to initial station.

El punto está localizado aproximadamente 6.5 Kmts. al Sur de San José; 4.5 Kmts. al S.E. de Alajuelita; 3 Kmts. al N.E. de Aserrí; 2 Kmts. al S.W. de Desamparados; en San Rafael de Desamparados. Está en un potrero propiedad de la señora Francisca de Solís, a 400 mts. al Norte de la Iglesia.

Para llegar, partiendo de San José, con rumbo Sur, aproximadamente 6 Kmts. hasta llegar a San Rafael de Deamparados. De la Iglesia tome una calle con rumbo al Norte, unos 400 mts. hasta llegar a una curva de la calle; aquí encontrará un portillo, se atravieza y a unos 25 mts., siempre con rumbo Norte, encontrará el vértice.

La estación es un disco de bronce de 9 centímetros de diámetro, colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale 0.05 mts. del suelo, estampado: RAFAEL, 1957.

El punto de referencia # 1 es un disco de bronce de 6 centímetros de diámetro, colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale 0.10 mts. del suelo y está 0.398 mts. más alto que la estación, estampado: RAFAEL, R.M.1, 1957.

El punto de referencia # 2 es un disco de bronce de 6 centímetros de diámetro, colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale 0.08 mts. del suelo y está 0.660 mts. más bajo que la estación, estampado: RAFAEL, R.M.2, 1957.

El Acimut está localizado aproximadamente 362 mts. del vértice, con rumbo S 07 W, en un potrero, y en propiedad del Sr. Elías Jiménez Castro; a 21 mts. al Este de la cerca Oeste de la calle y a unos 30 mts. del centro de un portillo de entrada al potrero, con rumbo N.E. encontrará el Acimut.

Detailed descriptions

El punto está localizado aproximadamente 5 Kmts. al N.E. de San José; 3.5 Kmts al Este de Santo Domingo de Heredia y 2 Kmts. al N.W. de San Vicente de Moravia. Está en la calle que va a los Sitios de Moravia hacia San Juan de Tibás, frente a la casa de habitación de don Juan Durán y al otro lado de la finca de Andrés Challe Sucs.

Para llegar, partiendo de la esquina N.E. de Moravia con rumbo Norte, hacia San Jerónimo de Moravia sobre carretera asfaltada, se recorren 1.9 Kmts. hasta llegar a la Pulpería "El Descanso" en Guayabal de Moravia; tome de aquí un camino de tierra al Norte, que conduce a Los Sitios de Moravia; a 450 mts. el camino se bifurca, se toma el que va al Norte (Derecha) y se continua 950 mts. hasta encontrar una nueva bifurcación (aquí se aprecia el talud), tome siempre al Norte 160 mts.

y llega a la casa de don Juan Durán, enfrente de la casa y a unos 20 mts. en un talud o meseta, está el punto en la calle.

La estación es un disco de bronce de 9 centímetros de diámetro, colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale a 0.06 mts. del suelo, estampado: TRINA, 1957.

El punto de referencia # 1 es un disco de bronce de 6 centímetros de diámetro colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale 0.08 mts. del suelo y está a 0.213 mts. sobre la estación, estampado: TRINA, R.M. 1, 1957.

El punto de referencia # 2 es un disco de bronce de 6 centímetros de diámetro colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale 0.08 mts. del suelo y está a 0.600 mts. sobre la estación, estampado: TRINA, R.M. 2, 1957.

El punto del acimut está en la finca de don Andrés Challe como a 6 mts. del camino y 30 mts. al N.E. de una casa que dista de la estación a 800 mts. aproximadamente con rumbo S 15 E. Es un disco de bronce de 9 centímetros de diámetro, colocado en un monumento de concreto prefabricado y empotrado en concreto, que sobresale 0.10 mts. del suelo, estampado: ACIMUT, TRINA, 1957.

En San Francisco de Guadalupe, la marca se encuentra, empotrada en el extremo Norte del pretil Este de pequeña alcantarilla, que está debajo del puente de San Francisco, a 1.5 metros al Este del eje de la ruta, y a nivel del pretil. Desde esquina SE de caja de alcantarilla al lado Oeste de la vía férrea, con rumbo al NSE a 4.5 metros; desde el poste 29 de la Milla 103, con rumbo al Sur a 13.5 metros, y desde esquina Oeste de caja de alcantarilla al lado Este de la vía férrea, con rumbo SO. a 2.5 metros. El eje de la ruta adyacente a la marca está a nivel; a 30 metros al Norte a 0.4 metros más alto, y a 30 metros al Sur a 0.4 metros más bajo.

Desnivel del puente a la vía a 7.0 metros más bajo.

En San José, la marca se encuentra a lo largo de la calle 17, entre avenidas 3 y 7, en el extremo Sur del bastión Oeste del puente del ferrocarril de Costa Rica, a 4.1 metros sobre el nivel de la calle 17 y a 6.6 metros al Oeste del eje de la ruta. Desde el costado Oeste del tanque de almacenamiento de petróleo de la Northern Railway Co. esta a una distancia de 29.4 metros con rumbo N 70 W, desde el extremo Norte del bastión Oeste a 9.2 metros con rumbo Sur franco y desde el extremo S.E. del alerón del mismo bastión a 5.6 metros con rumbo N 15 W. El eje de la ruta adyacente a la marca está a 4.1 metros más bajo; de ahí a 30 metros al Norte, 3.2 metros más bajo y a 30 metros al Sur, 4.4 metros más bajo.

Las diferencias de nivel se refieren a la marca.

PROYECCION LAMBERT PARA  
COSTA RICA

**APÉNDICE 2: Proyección Lambert facilitada por I.G.N. de Costa Rica**

GRADICULA DE COSTA RICA

1. GENERALIDADES

El sistema de coordenadas geográficas para Costa Rica se basa en la Proyección Lambert Conformante. Las líneas de esta proyección son rectas, excepto las meridianas que son curvas de igual longitud. Las líneas de esta proyección son rectas, excepto las meridianas que son curvas de igual longitud. Las líneas de esta proyección son rectas, excepto las meridianas que son curvas de igual longitud.

2. DESARROLLO DE LA PROYECCION LAMBERT

El desarrollo de la Proyección Lambert Conformante se basa en la hipótesis de que la Tierra es una esfera perfecta. La proyección se desarrolla sobre un cilindro que toca a la esfera en un punto. Las líneas de esta proyección son rectas, excepto las meridianas que son curvas de igual longitud. Las líneas de esta proyección son rectas, excepto las meridianas que son curvas de igual longitud.

3. NOTACION

Las abreviaturas de la Proyección Lambert se describen en la Figura 1. La notación utilizada es la siguiente:

- $P$  = punto de proyección
- $R$  = radio de la zona
- $R_0$  = radio de  $P$
- $r$  = radio de  $P'$
- $R_1$  = radio de origen (punto central)
- $R_2$  = radio de origen (límite exterior)
- $R_3$  = diferencia de longitudes entre el meridiano central y el meridiano de  $P$
- $R_4$  = longitud de la zona o el ángulo entre el eje de longitud y el eje de latitud =  $2\Delta\lambda$
- $R_5$  = zona de cuadrícula
- $R_6$  = distancia meridional desde el ecuador hasta la latitud de  $P$
- $R_7$  = distancia meridional desde el ecuador hasta la latitud de  $P'$
- $R_8$  = distancia meridional desde el ecuador hasta la latitud de  $P''$
- $R_9$  = distancia de  $P$

PROYECCION LAMBERT PARA COSTA RICA

## CUADRICULA DE COSTA RICA

### 1. GENERALIDADES

El sistema de coordenadas planas para Costa Rica se basa en la Proyección Cónica Conformante Lambert. Las tablas más abajo contienen los factores necesarios para convertir las coordenadas geográficas a coordenadas de cuadrícula y viceversa y también para calcular los factores de escala y acimutes de cuadrícula. Incluso son los factores para el cálculo por medio de logaritmos así como por máquina.

### 2. DESARROLLO DE LA PROYECCION LAMBERT

El concepto básico de la Proyección Cónica Conformante Lambert consta de un cono tangente al esferoide a lo largo del paralelo de latitud escogido para el origen. Para mejorar las características de escala en la cuadrícula es ventajoso reducir el cono tangente a un cono secante que corta el esferoide en dos paralelos de latitud, los que comunmente se llaman los paralelos normales. Estos se escogen para equilibrar aproximadamente el error de escala en la latitud de origen con respecto al error de escala en las latitudes de los límites del norte y del sud de la zona. Para conseguir esto, se multiplica los radios de todos los paralelos desarrollados por un factor constante de reducción que se llama generalmente el factor de escala en el origen. El error de escala llega a ser cero en los paralelos normales.

### 3. ANOTACION

Los elementos de la Proyección Lambert se representan en la Figura I. La anotación adoptada es la siguiente:

- P = punto en consideración
- O = origen de la zona
- $\phi$  = latitud de P
- $\lambda$  = longitud de P
- $\phi_0$  = latitud de origen (paralelo central)
- $\lambda_0$  = longitud de origen (meridiano central)
- $\Delta\lambda$  = diferencia de longitud desde el meridiano central hasta el meridiano de P
- $\theta$  = convergencia de los meridianos o el ángulo entre el norte de cuadrícula y norte verdadero =  $\angle BAP$
- GN = norte de cuadrícula
- m = distancia meridional exacta en el esferoide desde la latitud de origen hasta la latitud de P
- M = distancia meridional desarrollada en la proyección desde la latitud de origen hasta la latitud de P = OC
- FN = ordenada falsa

FE = abscisa falsa

$R_0$  = radio desarrollado del paralelo de origen = AO

R = radio desarrollado del paralelo de P = AC = AP =  $R_0 - M$

$\alpha$  = acimut geodésico

t = acimut plano (medido del norte de cuadrícula)

T = acimut geodésico proyectado (medido del norte de cuadrícula) } acimut de cuadrícula

Y = norte de cuadrícula de P = FP

Y' = norte de cuadrícula del punto en el meridiano central con la misma latitud que P = DC

Y'' = ordenada de curvatura = CB

Y''' =  $(R_0 + FN) - Y = AB$

X = abscisa de cuadrícula de P

X' = abscisa de cuadrícula de P desde el meridiano central = BP

$k_0$  = factor de escala en el paralelo de origen

k = factor de escala en la latitud de P

$\bar{k}$  = factor de reducción de largura = razón de la largura de cuadrícula de una línea a la largura geodésica

a = eje semimayor del esferoide

b = eje semimenor del esferoide

$e^2 = (\text{Excentricidad})^2 = \frac{a^2 - b^2}{a^2}$

$e'^2 = \frac{a^2 - b^2}{b^2} = \frac{e^2}{1 - e^2}$

$\eta^2 = e'^2 \cos^2 \phi$

$\rho$  = radio de curvatura del esferoide en el meridiano

$$= \frac{a(1 - e^2)}{(1 - e^2 \sin^2 \phi)^{3/2}}$$

$\nu$  = radio de curvatura de esferoide en el plano vertical o el normal al esferoide que termina en el eje menor

$$= \frac{a}{(1 - e^2 \sin^2 \phi)^{1/2}} = \rho(1 + \eta^2)$$

$\Delta 1''$  = diferencia tabular para un segundo de latitud o longitud

FIGURA 1

#### 4. INFORMACION BASICA RELATIVA A LAS CUADRICULAS DE COSTA RICA

|           |                               |                               |
|-----------|-------------------------------|-------------------------------|
| a. Origen | COSTA RICA NORTE              | COSTA RICA SUD                |
|           | $\phi_0 = 10^{\circ}28'N.$    | $\phi_0 = 9^{\circ}00'N.$     |
|           | $\lambda_0 = 84^{\circ}20'W.$ | $\lambda_0 = 83^{\circ}40'W.$ |

b. Unidad de medida: el metro

c. Esferoide

Estas cuadrículas se basan en el Esferoide Clark del año 1866. Los parámetros limitadores, a y b, se adoptan como exactos. La excentricidad y todos los demás elementos se calculan de ellos.

$$a = 6\,378\,206,4 \text{ metros}$$

$$b = 6\,356\,583,8 \text{ metros}$$

$$e^2 = 0,00676\,86579\,97291$$

d. Factor de escala en el origen:

$$k_0 = ,99995696 \text{ COSTA RICA NORTE}$$

$$k_0 = ,99995696 \text{ COSTA RICA SUD}$$

e. Localización aproximada (al minuto más cerca) de los paralelos normales:

9°56'N. y 11°00'N., COSTA RICA NORTE;

8°28'N. y 9°32'N., COSTA RICA SUD.

f. Coordenadas falsas del origen

Para evitar coordenadas de cuadrícula negativas en cualquier punto se asignan coordenadas arbitrarias al origen. Refiriéndose a estas, se las llaman ordenada falsa y abscisa falsa. Para la abscisa falsa se usa un múltiplo exacto de 100.000 metros para mayor facilidad de aplicación. No hay ventaja en usar un valor par para la ordenada falsa puesto que esta se incluye en los valores tabulares de Y' (= FN + M). Sin embargo, es ventajoso que el término  $R_0 + FN$  tenga un valor par porque esto es un constante usado en el cálculo. Por eso, se ha elegido el valor de FN para hacer de  $R_0 + FN$  un múltiplo exacto de 100.000 metros.

Las coordenadas falsas son las que siguen:

|                                |                                |
|--------------------------------|--------------------------------|
| COSTA RICA NORTE               | COSTA RICA SUD                 |
| FE = 500.000 metros            | FE = 500.000 metros            |
| FN = 271.820,522 metros        | FN = 327.987,436 metros        |
| $R_0 + FN = 34.800.000$ metros | $R_0 + FN = 40.600.000$ metros |

#### 5. FORMA Y CALCULO DE LAS TABLAS

Las funciones básicas para hacer los cálculos en la Proyección Lambert se dividen en dos grupos. Tabla I abarca las funciones de latitud y Tabla II las de longitud. Todas las funciones se muestran con intervalos de un minuto.

a. Tabla I

(1) Los valores de R y Y' se calcularon de las fórmulas:

$$R = R_0 + a_1 \Delta\phi + a_2 \Delta\phi^2 + a_3 \Delta\phi^3 + a_4 \Delta\phi^4 + a_5 \Delta\phi^5 + a_6 \Delta\phi^6$$

$$Y' = R_0 + FN - R \text{ donde}$$

$$R_0 = k_0 \nu_0 \cot \phi_0$$

$$\Delta\phi = \phi - \phi_0, \text{ dado en minutos de arco}$$

$$t = \tan \phi_0$$

$$d = \text{radianes por minuto de arco} = \frac{\pi}{10.800} = ,00029\,08882\,08666$$

$$a_1 = \frac{-d \nu_0 k_0}{1 + \eta_0^2}$$

$$a_2 = \frac{-3d^2 \nu_0 k_0 \eta_0^2 t}{2(1 + \eta_0^2)^2}$$

$$a_3 = \frac{-d^3 \nu_0 k_0}{6(1 + \eta_0^2)^3} (1 + 4\eta_0^2 - 3\eta_0^2 t^2 + 3\eta_0^4 + 12\eta_0^4 t^2)$$

$$a_4 = \frac{-d^4 \nu_0 k_0 t}{24(1 + \eta_0^2)^4} (1 + 3\eta_0^2 + 35\eta_0^4 - 45\eta_0^4 t^2)$$

$$a_5 = \frac{-d^5 \nu_0 k_0}{120(1 + \eta_0^2)^5} (5 + 3t^2 + 24\eta_0^2 + 15\eta_0^2 t^2)$$

$$a_6 = \frac{-d^6 \nu_0 k_0 t}{720(1 + \eta_0^2)^6} (21 + 12t^2)$$

|                                       |                                       |
|---------------------------------------|---------------------------------------|
| COSTA RICA NORTE                      | COSTA RICA SUD                        |
| $a_1 = -184.332,51238 \times 10^{-2}$ | $a_1 = -184.316,54609 \times 10^{-2}$ |
| $a_2 = -9,72746 \times 10^{-4}$       | $a_2 = -8,41218 \times 10^{-4}$       |
| $a_3 = -26,31931 \times 10^{-6}$      | $a_3 = -26,32437 \times 10^{-6}$      |
| $a_4 = -0,03497 \times 10^{-8}$       | $a_4 = -0,02998 \times 10^{-8}$       |
| $a_5 = -0,00564 \times 10^{-10}$      | $a_5 = -0,00561 \times 10^{-10}$      |
| $a_6 = -0,00002 \times 10^{-12}$      | $a_6 = -0,00002 \times 10^{-12}$      |

(2) Los logaritmos comunes de R se han calculados de la siguiente fórmula.

Ellos se han verificado por medio de los logaritmos de los R's calculados en (1) susodicho, de la tabla de Vega de 10 cifras.

$$\log R = \log R_0 - b_1 \Delta\phi - b_2 \Delta\phi^2 - b_3 \Delta\phi^3 - b_4 \Delta\phi^4 - b_5 \Delta\phi^5 \text{ en donde}$$

$$b_1 = \frac{\mu dt}{1 + \eta_0^2}$$

$$b_2 = \frac{\mu d^2 t^2}{2(1 + \eta_0^2)^2} (1 + 3\eta_0^2)$$

$$b_3 = \frac{\mu d^3 t}{6(1 + \eta_0^2)^3} (1 + 2t^2 + 4\eta_0^2 + 6\eta_0^2 t^2 + 3\eta_0^4 + 12\eta_0^4 t^2)$$

$$b_4 = \frac{\mu d^4 t^2}{24(1 + \eta_0^2)^4} (5 + 6t^2 + 19\eta_0^2 + 24\eta_0^2 t^2)$$

$$b_5 = \frac{\mu d^5 t}{120(1 + \eta_0^2)^5} (5 + 28t^2 + 24t^4 + 24\eta_0^2 + 140\eta_0^2 t^2)$$

$$\mu = \text{módulo de los logaritmos comunes} = ,43429\,44819$$

 b_3 &= -0,00000\ 03537 \times 10^{-6} & b_3 &= -0,00000\ 02982 \times 10^{-6} \\
 b_4 &= -0,00000\ 00023 \times 10^{-8} & b_4 &= -0,00000\ 00017 \times 10^{-8} \\
 b_5 &= -0,00000\ 00001 \times 10^{-10} & b_5 &= -0,00000\ 00001 \times 10^{-10}
 \end{aligned}$$

(3) El factor de escala se ha calculado de la fórmula  $k = \frac{R \operatorname{sen} \phi_0}{v \cos \phi}$

haciendo uso de los R'es calculados en (1) susodicho.

(4) El factor de escala logarítmico se ha calculado de la fórmula  $k = \log R + \log \operatorname{sen} \phi_0 + \operatorname{colog} v + \operatorname{colog} \cos \phi$ , haciendo uso del log R calculado en (2) susodicho y verificado por medio del logaritmo del k natural calculado en (3) susodicho.

(5) La diferencia tabular para un segundo ( $\Delta 1''$ ) es la diferencia de un minuto dividido por 60 expresada con dos cifras decimales adicionales.

#### b. Tabla II

Los valores de  $\theta$  se han calculados hasta 5 cifras decimales de segundos de la relación  $\theta = \Delta \lambda \operatorname{sen} \phi_0$ .  $\operatorname{Sen} \theta$ ,  $\tan \theta$ , y  $\tan \frac{\theta}{2}$  se han interpolados de las funciones trigonométricas naturales de 15 cifras de Andoyer (tabulados a intervalos de 10 segundos) y verificados por medio del cálculo del desarrollo de las potencias en serie de las funciones.

Todas estas funciones están arregladas en forma de tabla contra el argumento de la diferencia de longitud del meridiano central. Esta diferencia de longitud ( $\Delta \lambda$ ) se considera positiva al este del meridiano central y negativa al oeste. Las diferencias para un segundo de longitud están puestas igualmente en tablas para todas las funciones trigonométricas. Estas se encuentran en unidades de la décima cifra decimal.

### 6. CALCULO DE LAS COORDENADAS

#### a. Coordenadas de cuadrícula de coordenadas geográficas,—por máquina

Las fórmulas para el cálculo de X y Y son las siguientes:

$$\begin{aligned}
 X' &= R \operatorname{sen} \theta & Y'' &= X' \tan \frac{\theta}{2} \\
 X &= FE + X' & Y &= Y' + Y''
 \end{aligned}$$

R y Y' son funciones de latitud interpoladas de la Tabla I.  $\operatorname{Sen} \theta$  y  $\tan \frac{\theta}{2}$

son las funciones longitudinales interpoladas de la Tabla II.

Hay que advertir que cuando las coordenadas geográficas son dadas solamente hasta ,001'', no será posible obtener coordenadas de cuadrícula de precisión mejores que ,015 metro.

Una forma sugerida con un ejemplo de cálculo ya resuelto se representa en Figura 2.

#### b. Coordenadas geográficas de coordenadas de cuadrícula,—por máquina

Las fórmulas para el cálculo de  $\phi$  y  $\lambda$  son los siguientes:

$$\begin{aligned}
 X' &= X - FE & Y'' &= X' \tan \frac{\theta}{2} \\
 \tan \theta &= \frac{X'}{R_0 + FN - Y} = \frac{X'}{Y''} & Y' &= Y - Y''
 \end{aligned}$$

$R_0 + FN$  es el constante para cada zona de cuadrícula (34.800.000 metros para Costa Rica Norte y 40.600.000 metros para Costa Rica Sud).  $\Delta \lambda$  se obtiene de  $\tan \theta$  por interpolación inversa en Tabla II, y  $\phi$  se obtiene de Y' por interpolación inversa en Tabla I.

Hay que advertir que ,01 metro es el equivalente de ,0003 segundo. Por eso, X y Y hasta dos cifras decimales son necesarios para obtener  $\phi$  y  $\lambda$  hasta ,001''.

Una forma sugerida con ejemplo ya resuelto se encuentra en la Figura 3.

FIGURA 2

#### c. Coordenadas de cuadrícula de coordenadas geográficas,—por logaritmos

Las fórmulas para el cálculo de X y Y por medio del empleo de logaritmos son semejantes a aquéllas usadas en el método mecánico. Ellas son:

$$\begin{aligned}
 \log X' &= \log R + \log \operatorname{sen} \theta \\
 X &= FE + X' \\
 \log \theta &= \log \Delta \lambda + \log \operatorname{sen} \phi_0 \\
 \log Y'' &= \log X' + \log \tan \frac{\theta}{2}
 \end{aligned}$$

$$Y = Y' + Y''$$

Log R es tabulado en la Tabla I. Log  $\operatorname{sen} \theta$  y  $\log \tan \frac{\theta}{2}$  deben calcularse

haciendo uso de las funciones S y T. Estas se encuentran en la mayoría de las tablas logarítmicas y se emplean como sigue:

$$\begin{aligned}
 \log \operatorname{sen} \theta &= \log (\theta \text{ en segundos}) + S \\
 \log \tan \frac{\theta}{2} &= \log \left( \frac{\theta}{2} \text{ en segundos} \right) + T
 \end{aligned}$$
